Clinical History:

During a 2-week period between mid-October and November 2022, approximately 20 out of 470 Rambouillet sheep from a flock in southern California died; the flock had been moved into irrigated hay fields recently. Some of the affected animals were initially underweight and most had nasal discharge, labored breathing and frothy discharge from the mouth. Two adult sheep (1 and 2) were submitted to the San Bernardino laboratory of the California Animal Health and Food Safety laboratory system (CAHFS) for necropsy and diagnostic work up.

Follow-up questions:

1. Morphological diagnoses for figures 1-6.
2. Most likely cause based on clinical history and necropsy findings.
3. Name at least one other associated gross lesion you should expect in the hoof and other in the heart.
4. Name at least 1 associated microscopic lesion.
5. Name 5 important differential diagnoses for figures 3-5.
Answers to follow-up questions:

(1) Morphological diagnoses for figures 1-6.

(2) Most likely cause based on clinical history and necropsy findings.
Bluetongue virus (BTV). A collection of concomitant facts is suggestive of bluetongue (BT) disease:
- A previous history of access to irrigated outdoor pastures.
- Occurrence during fall in California.
- Multiple, non-proliferative, non-vesicular, ulcerative and necrotizing lesions in the alimentary tract, in combination with fatal cases of severe pulmonary edema.
- Mortality rates of <10%.

(3) Name at least 1 other associated gross lesion you should expect in the hoof and other in the heart.
In the hoof: Coronitis: with prominent hyperemia of the periople and swelling of the coronary band (Figure 7).
In the heart – Focal hemorrhage in the tunica media at the base of the pulmonary artery and/or hydropericardium.

(4) Name at least 1 associated microscopic lesion.
Expected microscopic lesions include microvascular thrombosis, edema and hemorrhages in sites with gross lesions; necrosis and ulceration of oral mucosae; and skeletal and cardiac muscle necrosis (Figure 8-11).

(5) Name five important differential diagnoses for figures 3-6.
Most of them are important notifiable viral diseases. On the top of the list would be foot-and-mouth disease (FMD; caused by an Aphthovirus) and peste des petits ruminants (PPR; Morbillivirus), followed by vesicular stomatitis (Vesiculovirus) and sheeppox (Capripoxvirus). Others could be photosensitization and contagious ecthyma (Parapoxvirus).
Discussion:

BTV serotype 11 (BTV-11) was detected by RT-qPCR from spleen in both sheep. FMD virus, PPR virus, contagious eczema virus, border disease virus, malignant catarrhal fever virus, respiratory syncytial virus, type D enterotoxemia (Clostridium perfringens epsilon toxin), Salmonella sp, and Mycoplasma sp. were ruled out via different ancillary tests during the diagnostic work up.

BTV causes BT, the most economically important, non-contagious and vector-borne arboviral hemorrhagic disease of domestic and wild ruminants (1,2,4,8). After being transmitted by midges or competent vectors of Culicoides spp., the virus replicates extensively in the endothelial cells of multiple organs, causing ischemic necrosis with ulceration, edema and hemorrhages (1,2). BTV is an Orbivirus within the family Reoviridae with a segmented RNA that has facilitated genetic shift and drift and the generation of up to 29 currently recognized serotypes not uniformly distributed around the world (5); some of these RNA segments have been associated with attenuated vaccine strains (2). The global distribution of serotypes has been limited to tropical/subtropical and temperate areas in the latitudinal band of 40ºN and 35ºS, according to the population dynamics of the Culicoides sp. vector (1,2,4,7). Generally, the disease is asymptomatic in sheep, goats and cattle in endemic areas (2,5). Lesions appear in sheep (specially in European breeds) following seasonal incursions of midges into cooler temperate zones adjacent to these latitudes, or in form of epizootics, when new serotypes associated with attenuated vaccine strains (2,7). Llamas and alpacas can also be affected by BTV, while African ruminants are highly resistant (2,5,7).

After inoculation, BTV replicates in regional lymph nodes (2,7), where there is dendritic cell necrosis, which contributes to delayed seroconversion and promotes ensuing viremia with viral distribution throughout most tissues carried by leukocytes, platelets and red blood cells (2,6). Affected sheep may be asymptomatic or suffer a fulminant disease characterized by fever, nasal discharge, labored breathing, hyperemia of oral and nasal mucosa, drooling and edema of the head (1-3,7). Animals with more prolonged clinical courses have focal hemorrhages in muzzle, lips and gums, ulceration of dental pad and hard palate and inconsistent congestion/cyanosis of the tongue, which coins the name of the disease. Resistance to move and lameness may be associated with swelling of the feet due to hyperemia and/or hemorrhage of the coronary band and also due to muscle necrosis (1-3,7). Some apparently recovered animals, can die suddenly due to severe progressive pulmonary edema that occur in later stages of fatal infections (2). Gross and microscopic lesions are secondary to direct virus-mediated endothelial damage and the indirect effect of vasoactive and proinflammatory mediators induced by host cells (2,3,8). There are ventral intermuscular and subcutaneous oedema and hemorrhagic effusions, pulmonary edema, hydrothorax, hydropericardium, hemorrhages of tunica media at the base of pulmonary artery, hyperemia, hemorrhages and/or ulceration of esophagus and pre-stomachs and skeletal and myocardial muscle necrosis, specially within the papillary muscle of the left ventricle (1,2,7). Abortion and fetal congenital defects, such as hydranencephaly in sheep and cattle and arthrogryposis, macroglossia, excessive gingiva or dwarf-like fetuses in cattle, have been associated with BTV, especially with vaccine attenuated strains and BTV-8 (2,7).

BTV-11 is one of the widely distributed serotypes in North America transmitted by C. sonorensis, together with BTV-10, BTV-13, BTV-17 (and, more recently, BTV-3) (1,5). BTV-1 and BTV-2 are transmitted by C. insignis and were considered restricted to the southeastern US, but in 2010, BTV-2 was detected in California (1,5). BT is endemic in ruminant livestock of California with high seasonality in late July to November and with a November-July interseasonality during which the virus survives in female, long-live adult midges (4). BTV can also induce severe disease in North American white-tailed deer, black-tailed deer, bighorn sheep, pronghorn antelope, and milder disease in elk and bison (2,7). Llamas and alpacas can also be affected by BTV, while African ruminants are highly resistant (2,5,7).
